EV Population & Market Performance and Insights Report

Prepared By: Mohamed Fouad
Role: Data Analyst

This report translates the EV dashboard into executive-level business implications. It focuses on market concentration, adoption drivers, pricing mix, vehicle eligibility, geographic concentration, and model-year momentum. The dataset is overwhelmingly Washington-centric, so the findings should be interpreted as a Washington EV-population view with selective external benchmarks.

Executive Highlights

3,454 Total EVs in dataset	**79.68%** Top 3 maker share	**63.00%** Mid-range segment share
69.43% CAFV eligible share	**65.03%** BEV share	**52.32%** King County concentration

• Market concentration is high: Tesla alone holds 46.93%, and the top three brands control 79.68% of the dataset.

• Adoption is mainstream, not premium-led: mid-range and economic vehicles make up 96.41% combined, while luxury and super-luxury together remain just 3.59%.

• Policy-aligned vehicles dominate the fleet: CAFV-eligible units account for 69.43% of all records and carry the clear range advantage in the dashboard.

• Geography is decisive: Washington represents 99.74% of records, with King County alone contributing 52.32% and the top three counties reaching 71.16%.

External Market Context

• Global electric car sales exceeded 17 million in 2024, with more than 20% share of global car sales (IEA, 2025).

• Washington had 223,995 registered EVs in 2024, up 34% from 2023; the state ranked third nationally by EV market share (WSDOT, 2024).

• Washington's sales and use tax exemption for certain clean-fuel vehicles and plug-in hybrids expired on July 31, 2025 (WA DOL).

1. Market Structure & Competitive Concentration

Company share tells a stronger story than raw counts. This is not a fragmented market; it is a leader-led market with clear concentration risk and competitive asymmetry.

Tesla contributes 46.93% of all EVs, making it 2.6x the size of Kia and 3.2x the size of BMW in this dataset.

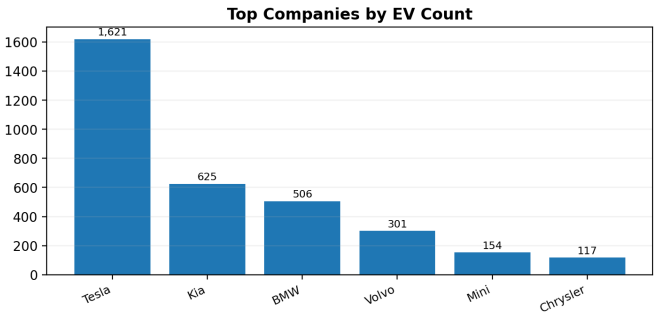
The **top 3 brands** (Tesla, Kia, BMW) account for 79.68%, while the **top 5** reach 92.85%. That means the long tail of the market contributes only 7.15% combined.

Executive implication: any operational, policy, or demand shock affecting Tesla materially changes the overall market picture. This is a concentrated portfolio, not a balanced one.

Model dependency is also high. Model S alone contributes 45.60% of all vehicles, and the top three models together account for 65.40%. The market is therefore concentrated at both brand and model level.

Top company shares

Tesla 46.93%
Kia 18.09%
BMW 14.65%
Volvo 8.71%
Mini 4.46%



Recommendation: present company market share and model dependency together in the dashboard narrative. That moves the conversation from ‘who sold more’ to ‘where is concentration risk and where is adoption concentrated’.

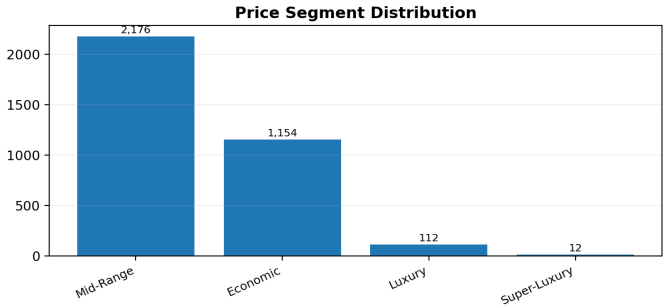
2. Product Mix, Price Segments & Vehicle Architecture

The category mix shows where the market has truly scaled: mainstream affordability. Mid-range vehicles represent 63.00% of the dataset and economic vehicles another 33.41%. Luxury remains niche and super-luxury is statistically negligible.

That matters strategically. It means EV adoption in this dataset is driven less by premium experimentation and more by practical consumer-market acceptance. When 96.41% of the fleet sits in mid-range or economic bands, pricing accessibility becomes a stronger adoption lever than brand prestige.

Powertrain architecture confirms the same direction. BEVs account for 65.03% of all units and for the overwhelming majority of total range volume. PHEVs remain relevant but secondary. This is a market trending toward full electrification rather than transition-stage hybrid dependence.

CAFV-eligible vehicles account for 69.43% of records. Combined with the dashboard's range advantage for eligible units, this suggests that policy-qualified vehicles are not only more common but also technologically stronger in practical terms.



Portfolio mix

Mid-Range: 2,176 (63.00%)
Economic: 1,154 (33.41%)
Luxury: 112 (3.24%)
Super-Luxury: 12 (0.35%)

BEV: 2,246 (65.03%)
PHEV: 1,208 (34.97%)

CAFV Eligible: 2,398 (69.43%)
Not Eligible: 1,056 (30.57%)

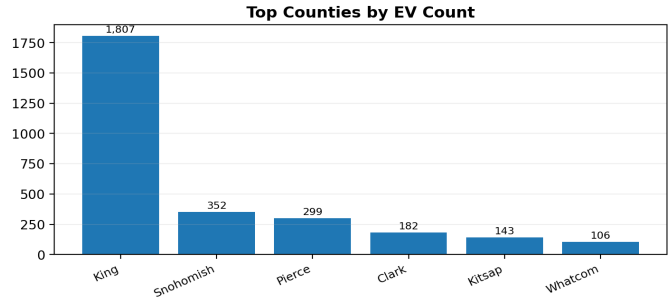
Recommendation: frame the market as ‘mass-market EV adoption with policy-supported product fit’. This is a stronger executive message than simply reporting that mid-range is the largest category.

3. Geographic Concentration & Deployment Logic

The dataset is functionally a Washington market view. Washington State holds 3,445 of 3,454 records, or 99.74% of the entire population. This is not a nationally balanced sample; it is a geographically concentrated EV ecosystem.

Within Washington, concentration becomes even sharper. King County alone holds 1,807 vehicles (52.32%), and the top three counties (King, Snohomish, Pierce) together reach 71.16% of the full dataset. Seattle alone contributes 573 vehicles (16.59%).

The pattern aligns with how EV adoption typically scales: dense urban areas, higher-income households, stronger charging access, and stronger policy adoption. The data therefore supports a deployment thesis, not just a location count.



Geographic takeaway

The practical addressable market is clustered around the Seattle metro and its adjacent counties. That means infrastructure, dealer strategy, incentive design, and targeted marketing should be optimized for regional density rather than broad-state uniformity.

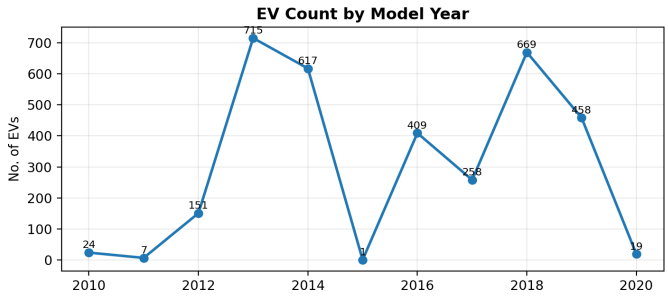
Top cities by count:
Seattle 573
Bellevue 198
Kirkland 123
Redmond 114
Vancouver 110

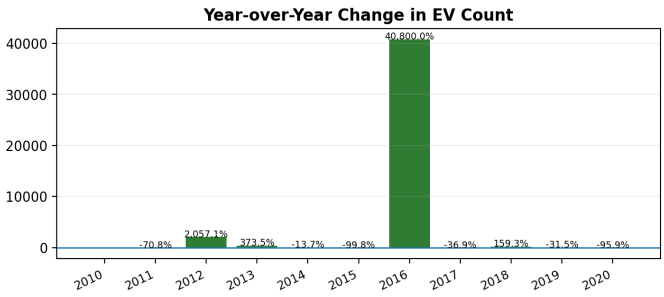
Recommendation: in the final presentation, avoid calling this a generalized U.S. EV market study. Call it a Washington-centric EV population analysis with strong King County concentration. That improves credibility immediately.

4. Model-Year Momentum, YoY Change & Data Quality Warning

The yearly view is the part executives will question most, because it mixes growth signals with clear structural anomalies. That is exactly why the analysis must go beyond counts into momentum and data reliability.

Observed trajectory from the dashboard: early years were small, 2012 marked the first real takeoff, 2013 delivered the largest scale-up, and later years showed sharp volatility rather than a smooth adoption curve.





Year	EV Count	YoY Change
2010	24	—
2011	7	-70.8%
2012	151	2,057.1%
2013	715	373.5%
2014	617	-13.7%
2015	1	-99.8%
2016	409	40,800.0%
2017	258	-36.9%
2018	669	159.3%
2019	458	-31.5%
2020	19	-95.9%

How to interpret this professionally:

- 2012 was the break-out year, with a ~2,057.1% jump from a very small 2011 base.
- 2013 added scale with another ~373.5% rise, making it the strongest expansion year by absolute volume.
- The 2015 collapse to 1 unit and the 2020 drop to 19 units are not analytically consistent with normal market evolution and should be flagged as likely data-coverage or extraction artifacts.
- Therefore, the yearly chart should be used to discuss *adoption phases and anomalies*, not to claim a stable time-series trend.

5. Senior-Level Recommendations

Reposition the narrative from counts to concentration
Lead with market share, top-3 control, and model dependency. Executives act on concentration and exposure, not just on volume.

Separate adoption story from data-quality story
Use the model-year chart to explain break-out periods and anomalies. Explicitly flag 2015 and 2020 as unreliable for strategic forecasting without validation.

Anchor pricing strategy in mainstream affordability
Since 96%+ of the portfolio sits in mid-range and economic bands, strategic messaging should emphasize accessible ownership rather than premium aspiration.

Prioritize BEV and CAFV-aligned offerings
BEVs dominate volume and CAFV-eligible vehicles dominate both count and range. Policy-qualified, full-electric products are the strongest fit with current market behavior.

Deploy geographically, not generically
Concentration in King County and the Seattle corridor suggests that charging, partnerships, promotions, and operations should be optimized for dense clusters first.

Use Tesla as a benchmark, not just a leader
Tesla's share and range leadership make it the category reference point. Competitor strategy should be framed in terms of narrowing Tesla's performance–price advantage.

Executive Conclusion

This dataset points to a clear executive story: EV adoption here is mainstream, policy-supported, BEV-led, and heavily concentrated in both geography and brand leadership. Tesla is not simply ahead; it structurally shapes the market. Mid-range and economic vehicles are the scale engine, while Washington—especially King County—is the geographic core.

The strongest version of this analysis does not stop at ‘who has more cars’. It explains where concentration sits, what part of the market is truly scaling, why eligibility and BEV architecture matter, and which time-series patterns are reliable enough for decision-making.
